1.0 Introduction

This report gives the results of a test for bias in the Crossville Coal clean coal sample system. A total of 17 sets of samples were collected from November 15, 2005 through February 1, 2006. Collection of stopped-belt reference samples and mechanical system save samples was performed by Rick Schubert, Quality Control Manager of Crossville Coal and Stephen Smith of Coalsmith Consultants.

This is a test of a sample system on the clean coal belt from a wash plant. Coal is mined using continuous miners in the Sewanee Seam. Raw coal goes through a rotary breaker with 4 inch openings. Coal is screened at 2 inch, and +2 inch is crushed and recycled to the screen. Two inch by 16 mesh coal is washed in a heavy medium cyclone circuit, with spirals for 16 mesh x 100 mesh. The 100 mesh x 0 coal is rejected and filtered in a belt press. The sampler tested is on the 36 inch wide, horizontal, clean coal belt.

Coal samples were dried, prepared, and analyzed at Standard Laboratories in Jacksboro, TN using ASTM methods of preparation and analysis. Procedures for the bias test conformed to the standard bias test procedure in ASTM D6518. Calculation of results of the test were performed using Datawolff Bias Test spreadsheet add-in script provided by Wolffware, Ltd. Test logs, coal analysis, calculations, and photographs of the system tested are attached.

2.0 Description of Sampling System

| | |
|-----------------------------|--------------------|
| Manufacturer..... | Ramsey Engineering |
| Year installed..... | 1997 |
| No. of sampling stages..... | 2 |
| Primary Sampling Stage | |
| Type..... | Sweep arm cutter |
| Drive..... | Electric |
| Cutter opening..... | 12 inches |
| Operating interval..... | 120 seconds |
| Primary Feeder | |
| Type..... | Chute |
| Crusher | |
| Manufacturer..... | Ramsey |
| Type..... | Minimill |
| Secondary Sampling Stage | |
| Drive System..... | Electric |
| Type..... | Sweep arm cutter |
| Cutter opening | 2 inches |
| Operating interval..... | 13 seconds |

3.0 Options Selected in Test Design

The bias testing procedure offers options to the user. The following options were selected:

- Coal Characteristics for the test were moisture, ar ash, ar sulfur, and ar Btu.
- An 80-minute test batch interval was chosen. This provided a target system save sample weighing 1000 grams at 8 mesh.
- A total of 30 test pairs were planned for and 17 pairs were collected.
- Two stopped-belt reference increments were collected and combined from each test batch of coal. Pre-selected random sample collection times (for each test batch) were followed during

the test. These reference samples were crushed to 8-mesh, riffled, and analyzed concurrently with the system save samples.

4.0 Results of the Test for Independent Differences

Individual differences between laboratory analyses of reference and laboratory analysis of system samples were examined to see if there was evidence that revealed they may not be independent. Should the assumption of independence not be true, conclusions drawn from the test using all sets of data to determine confidence intervals might be suspect.

The number of differences above (+) and below (-) the median difference, the low (l) and upper (u) table values, and the number of runs (r) found for each coal characteristic, are given below.

| | n ₁ , n ₂ | l, u | runs |
|------------|---------------------------------|------|------|
| Moisture | 8,8 | 5,13 | 7 |
| Dry Ash | 8,8 | 5,13 | 6 |
| Dry Sulfur | 4,8 | 3,i | 6 |
| AR Btu | 8,8 | 5,13 | 7 |

The number of runs for all characteristics falls within the closed interval (l,u) for p = 4. Thus, there is insufficient evidence to reject the assumption of independence of the individual bias test differences. Due to the precision of analysis of sulfur, being limited to two significant digits, resulted in an indeterminate upper limit for independence. Since 5 of the 17 sets showed a zero difference in sulfur, this reduced the number of runs (differences of zero are ignored in counting runs.). Therefore the significance of the independence of data is adequate, and this result was disregarded. We may proceed to calculate confidence intervals for bias.

5.0 Conclusions Regarding Bias

Walsh averages of the differences were calculated and confidence limits determined. Concluding statements are as follows:

If a chance error, which prior to the test had a maximum probability of occurring equal to no more than about 1 in 20, did not occur, biases of mechanically collected samples against stopped-belt reference samples lie within the closed intervals given below.

| | |
|------------|--------------------------------------|
| Moisture | $-1.485 \leq b(m) \leq 0.215$ |
| Dry Ash | $-0.970 \leq b(arash) \leq 0.265$ |
| Dry Sulfur | $-0.015 \leq b(arsulfur) \leq 0.015$ |
| AR Btu | $-171.5 \leq b(arhv) \leq 369.5$ |

B(m), b(arash), b(arsulfur), and b(arhv) represent moisture, ar ash, ar sulfur, and ar heating value biases, respectively.

The confidence interval for the four coal characteristics tested includes the value zero. Thus, this test offers insufficient evidence to reject a hypothesis of no bias of system samples against stopped-belt reference samples. Therefore the hypothesis of no bias in these parameters is accepted.

The point estimates of biases for the four parameters studied (the median value of Walsh averages) are as follows:

| | |
|-------------|--------|
| Moisture = | -0.64 |
| Ar Ash = | -0.265 |
| Ar Sulfur = | -0.005 |
| Ar HV = | +138 |

Respectfully submitted,

Stephen R. Smith
